

DOD TRAUMA REGISTRY DATA DICTIONARY

Version 3.2, Build 44 - Apr 2018, updated Nov 2019

Introduction & History

The Joint Trauma System (JTS) is the Department of Defense (DoD) authority for the military's trauma care system. The vision of the Joint Trauma System is that every Soldier, Sailor, Marine and Airman injured on the battlefield will have the optimum chance for survival and maximum potential for functional recovery. To achieve this vision, in 2006, the JTS implemented programs for data-driven trauma system development and improvement in addition to the collection of trauma data. As part of its data collection efforts, the JTS maintains a registry of trauma patients who received care at medical treatment facilities (MTFs). Since 2007, this registry – known as the DoD Trauma Registry (DoDTR) – has documented demographic, injury, treatment, and outcomes data for all trauma patients admitted to any DoD MTF, regardless of whether the injury occurred during on-going military operations, and is the largest military trauma data source in the world.

Development of the DoDTR began during the early years of the Global War on Terror (GWoT) when the need to systematically improve trauma care for combat wounded resulted in the impromptu creation of a demonstration registry, known then as the Combat Trauma Registry (CTR). The CTR was constructed by the Center for AMEDD Strategic Studies (CASS); trauma-related information was initially abstracted into it from paper medical records received from trauma nurse coordinators (TNCs) at Landstuhl Regional Medical Center (LRMC) in Germany. Shortly after the demonstration program started, the Army Surgeon General approved its transition to an operational mode, leading to the formation of the Joint Theater Trauma System (JTTS) and, eventually, the Joint Trauma System (JTS).

In 2006, the JTTS was tasked with developing the Joint Theater Trauma Registry (JTTR), the successor to the CTR. The first version of the JTTR was created using the National Trauma Data Bank (NTDB) as a template and a commercial, off-the-shelf product manufactured by Digital Innovation, Inc for the database. Once completed, legacy data previously collected for the CTR was migrated to the new Windows®-based JTTR, and staff located at LRMC started abstracting data directly into this version beginning in early 2007. Later that year, TNCs were also deployed to theater to collect trauma data using a "store and forward" adaptation of the JTTR. By fall 2008, data were being abstracted into a second version of the JTTR, not only by JTS staff at LRMC and TNCs in theater, but also abstractors located at Fort Sam Houston in San Antonio, TX.

Over the next several years, the JTTR evolved to capture data more specific to evaluating military policies, processes, and practices, and a web-based version was released in October 2011 for use by all DoD MTFs interested in providing data for the registry. Since December 2014, abstraction of all theater records has been centralized at the JTS headquarters in San Antonio. Records of patients treated at MTFs outside the continental U.S. (i.e. LRMC (Role 4 OCONUS)) and MTFs in the continental U.S. (i.e. Role 4 CONUS) are typically abstracted by trained staff at the treatment facility, although JTS staff may provide assistance when needed.

To date, more than 400 variables are captured in the DoDTR, abstracted from original paper and/or electronic records. Sources of data include, but are not limited to, Tactical Combat Casualty Care (TCCC) cards, patient care reports (PCRs), after action reports (AARs), facility medical records, Defense Enrollment Eligibility Reporting System (DEERS), Theater Medical Data Store (TMDS), Patient Administration Systems and Biostatistics Activity (PASBA), and TRANSCOM Regulating and Command & Control Evaluation System (TRAC2ES). Data are abstracted, when possible, for the entire continuum of acute care (i.e., care in the field at the point of injury through care rendered at role 4 CONUS MTFs, such as Walter Reed National Military Medical Center and Brooke Army Medical Center in the continental U.S.) As of April 2018, the main registry has over 80,000 distinct injury events and more than 130,000 trauma records that can potentially be used to better understand the burden of injury, morbidity, and mortality.

This document provides a list of the available data files and detailed descriptions of the variables contained in each file. Variables where <10% of the applicable population has a missing value or where the integrity of the data is questionable are not included. SAS® and STATA® sample programs are available to help researchers with merging files and recoding variables. Please be aware that the JTS does not provide statistical support and does not assist with analyses for research projects.

Inclusion/Exclusion Criteria

Patients included in the DoDTR:

- Any trauma casualty, designated by one of the above trauma diagnosis codes, treated at a Role 2 or higher Medical Treatment Facility (MTF) within 72 hours of injury (time rule applies to initial facility seen within the continuum of care) that meets ONE of the following conditions:
 - 1. Admission to Inpatient Status
 - 2. Transfer from ED/OR to another MTF for trauma care (excludes outpatient clinics)
 - 3. Trauma Deaths processed (record generated) at Role 2 or higher facility including:
 - Killed in Action (KIA)
 - Dead on Arrival (DOA)
 - Died of Wounds (DOW)
- Traumatic Brain Injury patients with a defined head trauma diagnosis code treated at a Role 2 or higher MTF/Civilian Hospital, regardless of when injury occurred or disposition status.
- Role 4/5's: Patients who sustained injury and do not meet above criteria may be entered into the DoDTR at the discretion of each facility.
- Patients remain eligible for inclusion as long as they remain in a MTF inpatient status for trauma care. Once the patient is discharged from acute care or permanently transferred to a non-MTF facility, data capture stops.

Patients excluded from the DoDTR:

- Rehabilitation ONLY patients.
- Patients who are boarded or remain overnight at a facility awaiting transfer to another MTF who do not receive medical treatment
- Military working dogs, contract, host nation
- Psychological admissions
- Same day surgery patients: Do NOT include outpatients undergoing same day surgical procedures. This includes patients admitted to the medical/ surgical ward for recovery only.
- Missing definitive trauma Dx (symptoms only)
- Planned follow-up procedure admissions. Example: Local nationals returning for IVC removal. If the MTF elects to capture removal of IVCs, place a note in the Memo field of the original DoDTR record.
- Medical Admissions: All non-trauma related admissions to include patients who have had recent traumatic injuries but are not being admitted for treatment of those injuries.

DoDTR inclusion criteria

^{*}Role 4 CONUS & OCONUS MTFs have the discretion to include patients in DoDTR who do not meet inclusion criteria.

Trauma diagnosis codes

- Trauma codes in the range: ICD-9 CM 800-959.9; ICD-10 CM S00-T88.
- Near drowning/drowning if related to injury (ICD-9 994.1; ICD-10 T75.1XXA)
- > Inhalation Injury (ICD-9 987.9; ICD-10 T59.***A)

Analytic & Data Limitations

Data Verification and Quality Assurance/Quality Checks

Validation checks were built into the abstraction process in 2007. This function verifies required fields are populated and will indicate if the data entered is out of the expected range.

Data are routinely examined for discrepancies and erroneous entries.

After record abstraction, data are reviewed by JTS QA staff for accuracy and completeness. A random sample of abstracted records are selected for QA on a weekly basis. Edits are made to some variables to ensure the completeness, consistency, and analytic usefulness of the data. Edits are also made, when necessary, to address data Operations Security (OPSEC) and Public Health Information (PHI) disclosure concerns.

The Data Acquisition Branch of the DoDTR is continually cleaning and standardizing the data to improve data quality.

Additional QA/QC practices include completing DoDTR-integrated range and validation checks during data abstraction, routine assessments of inter-rater reliability, scheduled and ad hoc validation reports, and the correction of data discrepancies. Identified discrepancies may be reported to DAB by any end-user; they are then placed in a queue for review and, if warranted, corrected in the DoDTR. Finally, a comprehensive review and assessment of all registry data, beginning with the most recent data and moving retrospectively and systematically through previously captured data, is being conducted to validate it against source documentation. Data for injury events that occurred in 2010 to present have been reviewed and validated.

Essential Information for the Appropriate Use and Analysis of DoDTR Data including Limitations

There are numerous advantages of using registry data for medical research. However, investigators must also be aware of the limitations that generally apply to all registries as well as those specific to individual registries, such as the Department of Defense Trauma Registry (DoDTR). Although registries can be useful in conducting research by identifying patient cohorts that meet particular criteria, they are not primary research tools and are not designed to answer any specific scientific question. Data collection for registries is typically more passive than that for other types of epidemiology studies, and missing data can present a greater concern. Moreover, the value of a registry is inherently dependent on the quality of the data it contains. Because the DoDTR includes only a selective sample of data (from the subset of participating US military MTFs) for only a selective sample of the entire target population, inferences from statistical analyses of

DoDTR data should be made only with caution and after careful consideration of the sources of error and bias.

The DoDTR is an incident registry. A single patient may have multiple injury events captured in the registry depending on the number of incident injuries for which they were admitted for treatment. Data for each injury event is collected by manually abstracting predetermined information from paper records and various electronic information systems, which often contain conflicting accounts of patient care and treatment. To reconcile disparate information, the Data Acquisition Branch of the JTS has developed business rules that guide data abstraction and prioritize sources of information. Nevertheless, because much of the data in the DoDTR is abstracted from the medical record, it is only as complete as the information recorded by providers.

Analytic & Data Limitations

More specifically, while a value of "yes" can be considered confirmed information, a value of "no" does not always mean the patient did not receive the treatment, procedure, etc. It could also simply mean the information was not documented. If the quality or completeness of the information available for abstraction differs by facility, the data may be susceptible to information bias. Additionally, while every attempt is made to document the entire continuum of acute care, a patient's final disposition may not be known, particularly if the patient was a local national or was transferred to an MTF that does not contribute to the registry or any U.S. civilian facility. Researchers should be mindful that DoDTR data is not abstracted in real-time, and complete data for patients injured in the most recent calendar quarter may not yet have been abstracted or reviewed for errors due to reporting delays.

The population captured by the DoDTR is not a random sample of trauma patients treated at medical treatment facilities, and the DoDTR data are, therefore, subject to selection bias. Trauma logs of patients treated in theater, which are used to identify casualties to be included in the DoDTR registry, are submitted voluntarily to the JTS. In addition, trauma-related data from MTFs outside of theater are captured only for facilities that willingly choose to contribute to the registry. Of the 42 U.S. Army, Navy and Air Force MTFs outside of theater that currently provide emergency services, 7 submit data to the registry. Of these, four are Army treatment facilities. At present, the DoDTR does not include any maritime data.

In general, DoDTR data are comprised of a disproportionate number of injuries admitted to the larger Role 3 facilities in theater. This is primarily an effect of the original inclusion criteria, (see Inclusion Criteria & Data QA-QC tab), which has considerably changed over time. Initially, only patients admitted to a Role 3 MTF were included in the registry (i.e., patients that did not require evacuation to a Role 3 or died at a Role 2 or lower-level MTF were excluded). Beginning in 2015, patients treated solely at Role 2 MTFs were included in the registry

when records documenting care were available. Deaths that occur in a prehospital setting before being transported to a Role 3 for processing are often not included in the registry owing to a lack of documentation. Consequently, when data from the DoDTR are analyzed alone, survival bias may adversely affect the findings.

How data have been captured in the registry has also changed over time. Prior to 2012, care provided at prehospital facilities (i.e., combat medics (Role 1a), battalion aid stations (Role 1b), and clinics (Roles 1b and 1c) was documented in separate trauma records. For example, if a patient was treated at point of injury, a clinic, and a Role 3 facility, there would be a unique trauma record for each of these that captured information on patient vitals, procedures, and other care provided. Beginning in 2007, prehospital care provided at a Role 1a or 1b MTF was no longer documented in separate trauma records but, rather, included within the record for the first facility with surgical capabilities at which the patient received treatment. Prehospital care provided at a 1c was also captured within the record for the first surgical capability starting in 2012. Under this system for capturing prehospital data, the patient from the same example would only have one trauma record, and it would be for the Role 3 MTF. Any other care provided by the medic or at the clinic would be captured in the Arrival Transport section of the casualty's Role 3 trauma record. Researchers should also be aware that the DoDTR does not capture duplicate codes for diagnoses or procedures on the same patient at a single facility. For example, if an individual had multiple CT scans while admitted to the ICU at a given facility the ICD-9/10 procedure code will only be recorded once for that facility.

Data from the DoDTR is provided in both wide and long formats depending on the data file. The *Demographic & Injury* data file will be in wide format (i.e., one record per person), whereas all other files will be in long format (i.e. there may be more than one record per person).

Analytic & Data Limitations

Data in the *Demographic & Injury* file can be mapped to data in other DoDTR data files using the DoDTR_ID variable only. However, data in files with a wide format must be mapped using both the DoDTR_ID and Trauma_ID variables. The Trauma_ID variable should never be used by itself to map data from the different files.

Prior to being analyzed, DoDTR data must be cleaned and recoded. The data will contain outliers and missing values that should be carefully examined. Missing values most often occur when patient information is not recorded or documented at the time of patient care and may distort study results. The proportion of missing data will differ by variable and year, and possibly MTF. Data included in the DoDTR prior to 2008 are especially incomplete, as much of it was not abstracted to current standards and very little of it has been validated via the Data Acquisition Branch's ongoing retrospective audit of all DoDTR records. Accordingly, end-users should evaluate the degree of missingness in their dataset. As a general rule, if 10% or less of the data for a variable are missing roughly equally across the primary comparison groups, it is usually acceptable to analyze the data without further assessment or adjustment. However, if more than 10% of the data for a variable are missing, differences in missingness across relevant characteristics should be evaluated. For some variables, it may be possible to impute values for the missing data, by either single or multiple imputation. Whether missing data are excluded from an analysis or values are imputed, the effects of missing data on study results should be investigated by conducting sensitivity analyses.

When running the **SAS**® sample program provided, users will need to do the following:

- 1) Modify infile statement identifying saved location and format (i.e. txt, csv) of requested data file
- 2) Add format statements for date and time variables to change them to SAS date and times (i.e. ddmmyy10., time6. etc.)

In all DoDTR datasets supplied after **April 2018**, missing values are denoted in the following way:

• a blank space for **character** and **numeric** variables

"Not Applicable" is another type of data value to consider during analysis. This type of value applies if, at the time of patient care documentation, the information captured did not pertain to the patient. For example, discharge vitals are only recorded for patients discharged alive and are not applicable to deceased patients.

In all DoDTR datasets supplied after **April 2018**, "Not Applicable" values are denoted in the following way:

- a value of "8," "88," "888," etc. depending on the number of digits in the variable value range for **numeric** variables, or
- the text "n/a" for character variables

Detailed information on valid values for each variable are provided in the sections following the Summary of Changes. Researchers should make certain the data being analyzed for their study are consistent and valid.

At present, automated data cleaning is limited with regard to inconsistencies between variables in order to avoid incorrectly changing or deleting values. There are, for example, instances where the number of vent days is greater than the facility length of stay or the injury date, and it is up to researchers to decide how to use that information.

Finally, due to on-going, regularly scheduled audits of all DoDTR records, results from similar statistical analyses conducted at different times or by different data analysts using DoDTR data from the same time periods may turn out to be less reproducible than expected. The DoDTR data are constantly being reviewed and updated.
